Abstract

ASTRO-GEODETC Observatory in Józefosław (near Warszawa) is equipped with two gravimeters for different purposes. Continuously recording LCR EF20 spring gravimeter (since 2000) serves for observation of accurate local tidal coefficients and investigation of environmental effects such as atmospheric and ocean influence on gravity. FG2 no. 230 ballistic gravimeter (since 2005) is operated periodically - once a

month. Frequently measurements allow us to identify non-tidal gravity changes caused mainly by local and continental hydrology. In this paper we present some advantages of using two types of gravimeters. During calibration process the gravimeter records from ballistic gravimeter are used for determination of scale factor of spring gravimeter. On the other hand ballistic gravimeter utilizes local tidal model determined from spring gravimeter for obtaining non-tidal series. Long series of synchronous measurements were used for determination of background noise, atmospheric

(altitude factor), ocean and hydrological effect on gravity changes. The results from both gravimeters is presented and their agreement is discussed.

Figure 1. LCR and FG2 gravimeters in Józefosław.

Activities

Calibration of spring gravimeter using AG measurements

Raw observations of LCR are presented in Fig. 2 along with FG2 periodically taken measurements.

Figure 2. Raw observations of LCR gravimeter. Vertical bars represent FG2 measurements.

The results for particular series and AG measurements length are presented in Fig. 3.

Figure 3. Scale factor values - upper graph, for sessions of minimum 2 days length from AGG series. Number of FG2 measurements days and RMS of LCR residuals.

Tidal parameters determination

Tidal gravity parameters in diurnal and semi-diurnal bands are computed using international standard data processing techniques. We used 40 months (2007-2010) of continuous gravity measurements. The standard deviation of least square adjustment reached 0.08 $\mu\text{m/s}^2$.

Conclusions

MEASUREMENTS with LCR-ET and FG2 provide high quality gravity values. Carefulness in processing and long series of collected data al-

Figure 4. Amplitude factors, difference in amplitude factors between the Mean-Offset tidal model and phase for non-tidal constituents extracted from measurements (pressure correction applied).

Atmosphere influence on gravity

We computed pressure advance as simple regression coefficient on basis of LCR measurements. Using moving data window we examined seasonal behaviour of pressure advance factor which is presented in Fig. 5.

Figure 5. Seasonal variation of atmospheric pressure advance factor and difference between using mean and four dependent values for gravity correction.

Ocean loading

In Fig. 4 one can see significant discrepancies between determined and predicted from model body tide especially for J_2 constituent. Computing indirect effect using mean ocean ocean models (we do not differentiate them here, as they give similar results) greatly reduces this differences.

lowe for investigation in weak environmental signals - pressure and ocean loading, hydrological signals. Combining those results with records from different instruments (meteo, GNSS, water table level and soil moisture observations) in Józefosław Observatory makes it unique place in Poland for

Figure 6. Phase plots for residual values (abstracted body tide, blue color) and residuals corrected for ocean loading using mean ocean models (other rank).

Hydrological effects

AG values show periodical variation. Part of seasonal signal can be explained by local and global water storage (Fig. 7).

Figure 7. AG measurements compared to gravity change due continental water storage and local water table level variation.

Background noise

We investigated in background noise (containing instrumental noise) on basis of raw observation (1 min sampling). Here we present daily standard deviation from records where tide and polynomial of 9th degree were subtracted.
